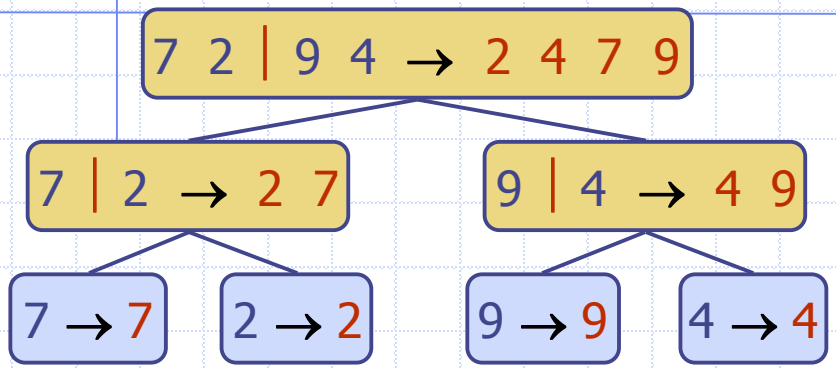
Lesson 4
Merge Sort: Collapsing Infinity To a Point



Wholeness of the Lesson

Merge Sort is a Divide and Conquer sorting algorithm which, by overcoming the limitations inherent in inversion-bound sorting algorithms, is able to sort lists in $O(n \log n)$ time, even in the worst case. The Divide and Conquer strategy is an example of the simple principle of "Do Less and Accomplish More." This technique makes it possible to break the inversion-bound barrier for sorting alrgorithms, to obtain very fast running times.

MergeSort: A Divide-and-Conquer Algorithm

- Recall: Divide-and conquer is a general algorithm design paradigm. MergeSort implements this design:
  - Divide: divide the input data S in two disjoint subsets S_1 and S_2
  - Conquer: solve the subproblems associated with S_1 and S_2
  - Combine: combine the solutions for S_1 and S_2 into a solution for S
- Merge-sort is a sorting algorithm based on the divide-and-conquer paradigm

Merge Sort time complexity

- Unlike Other sorts like Selection, Bubble and Insertion which has $O(n^2)$ time complexity
- Merge sort has $O(n \log n)$ time complexity in worst case, which means Merge sort is much faster than other sorting algorithm we studied so far

Merge-Sort

- Merge-sort on an input sequence S with n integers consists of three steps:
  - Divide: partition S into two sequences S_1 and S_2 of about $n/2$ elements each
  - Conquer: recursively sort S_1 and S_2
  - Combine: merge S_1 and S_2 into a single sorted sequence

Algorithm *mergeSort*(S)
  Input sequence S with n
  Output sequence S sorted
  if $S.size() > 1$ **then**
    $(S_1, S_2) \leftarrow partition(S, n/2)$
    mergeSort(S_1)
    mergeSort(S_2)
    $S \leftarrow merge(S_1, S_2)$
  return S

Merging Two Sorted Sequences

- The *combine* step of merge-sort consists of merging two sorted sequences A and B into a sorted sequence S containing the union of the elements of A and B
- Merging two sorted arrays, each with $n/2$ elements takes $O(n)$ time

Algorithm *merge*(A, B)

Input sorted sequences A and B with $n/2$ integers each

Output sorted sequence S of $A \cup B$

$S \leftarrow$ empty sequence

while $\neg A.isEmpty() \wedge \neg B.isEmpty()$ **do**
  if $A.first() <= B.first()$ **then**
    $S.insertLast(A.remove(A.first()))$
  else
    $S.insertLast(B.remove(B.first()))$

while $\neg A.isEmpty()$ **do**
  $S.insertLast(A.remove(A.first()))$

while $\neg B.isEmpty()$ **do**
  $S.insertLast(B.remove(B.first()))$

return S

- Merge

Implementation of Merge

```
int[] theArray;   //this array is populated with two sorted sections of ints
public void merge(int[] tempStorage,
                  int lowerPointer,
                  int upperPointer,
                  int upperBound) {
   int j = 0; //tempStorage index
   int lowerBound = lowerPointer;
   //total number of elements to rearrange
   int n = upperBound - lowerBound + 1;
   //view the range [lowerBound,upperBound] as two arrays
   //[lowerBound, mid], [mid+1,upperBound] to be merged
   int mid = upperPointer -1;
   while(lowerPointer <= mid && upperPointer <= upperBound){
      if(theArray[lowerPointer] <= theArray[upperPointer]){
          tempStorage[j++] = theArray[lowerPointer++];
      }
      else {
          tempStorage[j++] = theArray[upperPointer++];
      }
   }
```

Merge (continued)

```
    //left array may still have elements
    while(lowerPointer <= mid) {
       tempStorage[j++] = theArray[lowerPointer++];
    }
    //right array may still have elements
    while(upperPointer <= upperBound){
       tempStorage[j++] = theArray[upperPointer++];
    }
    //replace the range [lowerBound,upperBound] in theArray with
    //the range [0,n-1] just created in tempStorage
    for(j=0; j<n; ++j) {
       theArray[lowerBound+j] = tempStorage[j];
    }
}
```

Implementation of MergeSort, In-Place

```
class MergeSort {
   int[] theArray;

   //public sorter
   public int[] sort(int[] input){
       int n = input.length;
       int[] tempStorage = new int[n];
       theArray = input;
       mergeSort(tempStorage,0,n-1);
       return theArray;
   }
```

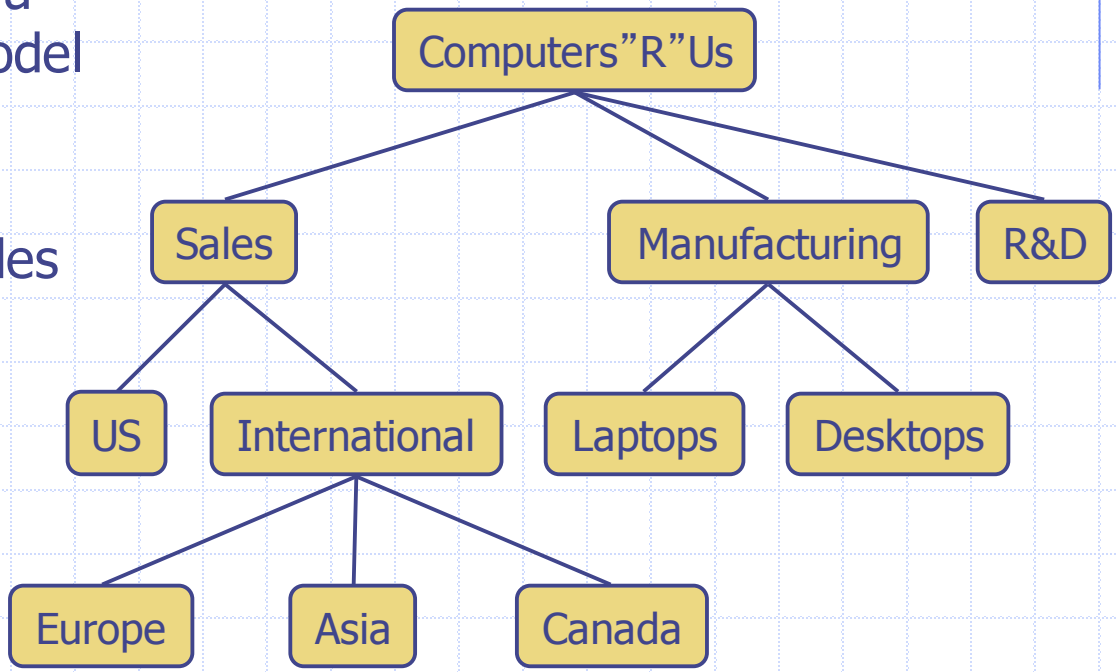
(continued)

```
    void mergeSort(int[] temp, int lower, int upper) {
        if(lower==upper){
            return;
        }
        else {
            int mid = (lower+upper)/2;
            mergeSort(temp,lower,mid);
            mergeSort(temp,mid+1, upper);
            merge(temp,lower,mid+1,upper);

        }
    }
}
```

Trees

- In computer science, a tree is an abstract model of a hierarchical structure
- A tree consists of nodes with a parent-child relation
- Applications:
  - Organization charts
  - File systems
  - Programming environments



Merge-Sort Tree

- An execution of merge-sort may be depicted by a binary tree
  - each node represents a recursive call of merge-sort and stores
    - unsorted sequence before the execution and its partition
    - sorted sequence at the end of the execution
  - the root is the initial call
  - the leaves are calls on subsequences of size 0 or 1

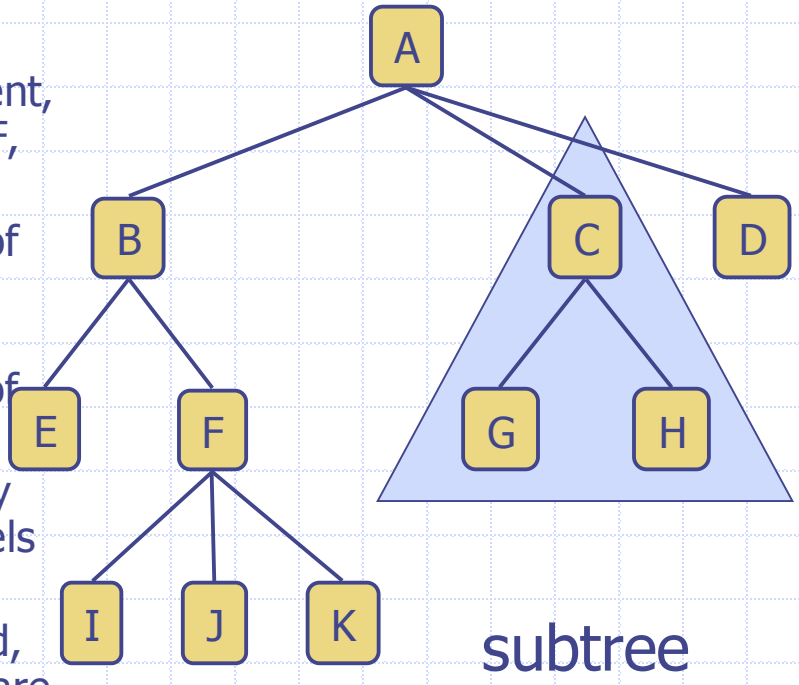
Tree Terminology

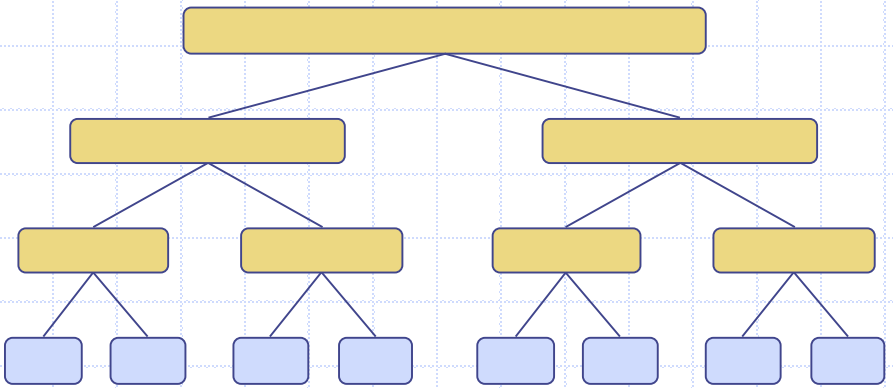
- ***Root***: node without parent (A)
- ***Internal node***: node with at least one child (A, B, C, F)
- ***Leaf*** (or "external") ***node*** is a node without children (E, I, J, K, G, H, D)
- ***Ancestors of a node***: parent, grandparent, grand-grandparent, etc. (ancestors of K: F, B, A)
- ***Depth of a node***: number of ancestors of the node (depth of K = 3)
- ***Levels of a tree***: Level n of a tree is the set of all nodes having depth n. (Level 1 of this tree is {B, C, D})
- ***Height of a tree***: maximum depth of any node (height of tree = 3). Note: Num levels = height + 1.
- ***Descendant of a node***: child, grandchild, grand-grandchild, etc. (descendants of B are E, F, I, J, K)
- ***Subtree***: tree consisting of a node and its descendants



Alternate Analysis of Merge-Sort

- The height h of the merge-sort tree is $O(\log n)$
  - at each recursive call we divide the sequence in half (approximately)
  - The overall amount of work done at each level is $O(n)$
- Thus, the total running time of merge-sort is $O(n \log n)$

depth	#seqs	size
0	1	n
1	2	$n/2$
i	2^i	$n/2^i$
…	…	…

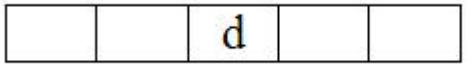


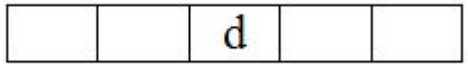
Main Point

By using a Divide and Conquer strategy, MergeSort overcomes the limitations that prevent inversion-bound sorting algorithms from performing faster than n^2. An essential characteristic of this strategy is the relationship of whole to part – wholes are successively collapsed and the collapsed values are combined to produce a new whole. This is different from the incremental approach of inversion-bound algorithms. We see here an application of the MVS principle of *akshara:* Creation arises in the collapse of the unbounded value of wholeness to a point.

Handling Duplicates

- Issue arises during the merge step – if element in left half equals element in right half, insert element in left half first





- Stability

Name	Date Received
. . .	. . .
Dave	11/5/2003
Dave	12/1/2004
Dave	1/8/2005
Dave	4/2/2006
. . .	. . .

If you first sort by date (name secondary), then later by name (date secondary), you want dates related to a single name to remain sorted.

Handling Duplicates (cont)

- Definition. Suppose

$$S = <(k_0,e_0), (k_1,e_1),\ldots,(k_n,e_n)>$$

is a list of pairs with keys k_0, k_1, …, k_n. A sorting algorithm is *stable* if, whenever it is the case that (k_i, e_i) precedes (k_j, e_j) before sorting (so that $i < j$) and $k_i = k_j$, then it continues to be true after sorting by keys that the pair (k_i, e_i) precedes (k_j, e_j)

Stable sorting does not change the order of duplicates

Stability of Sorting Algorithms

- MergeSort is stable because of our strategy for handling duplicates during Merge

Time Complexity of Merge Sort

$$T(n) = \begin{cases} C & , \text{if } n = 1 \\ 2T(n/2) + (C_2+C_3)n + (C_1+C_4) & \end{cases}$$

$$T(n) = \begin{cases} C & , \text{if } n = 1 \\ 2T(n/2) + c'n + c'' & \end{cases}$$

$$T(n) = \begin{cases} C & , \text{if } n = 1 \\ 2T(n/2) + c'n + c'', & \text{if } n>1 \end{cases}$$

$$T(n) = \begin{cases} C & , \text{if } n = 1 \\ 2T(n/2) + c'n, & \text{if } n>1 \end{cases}$$

```
Mergesort (A)
{
  n ← length(A)                          } C1
  if (n < 2) return n
  mid ← n/2
  left ← array of size(mid)
  right ← array of size(n-mid)
  for i ← 0 to mid-1                     } C2·n
    left[i] ← A[i]
  for i ← mid to n-1
    right[i-mid] ← A[i]
  T(n/2) ⇐ Mergesort (left)              } C3·n + C4
  T(n/2) ⇐ Mergesort (right)
  Merge(left, right, A)
}
```

Time Complexity of Merge Sort

$$T(n) = \begin{cases} c & , \text{ if } n = 1 \\ 2T(n/2) + c'n & , \text{ if } n > 1 \end{cases}$$

$$T(n) = 2\left\{2T(n/4) + c' \cdot \frac{n}{2}\right\} + c'n$$

$$= 4T(n/4) + 2c'n$$

$$= 4\left\{2T(n/8) + c' \cdot \frac{n}{4}\right\} + 2c'n$$

$$T(n) = 4T(n/4) + 2c'n$$

$$= 8T(n/8) + 3c'n$$

$$= 16T(n/16) + 4c'n$$

$$= 2^k T(n/2^k) + k \cdot c' \cdot n$$

$$\frac{n}{2^k} = 1 \Rightarrow 2^k = n$$

$$\Rightarrow k = \log_2 n$$

Time Complexity of Merge Sort

$$T(n) = \begin{cases} c & , \text{ if } n = 1 \\ 2T(n/2) + c'n & , \text{ if } n > 1 \end{cases}$$

$$\begin{aligned} T(n) &= 4T(n/4) + 2c'n \\ &= 8T(n/8) + 3c'n \\ &= 16T(n/16) + 4c'n \\ &= 2^k T(n/2^k) + k \cdot c' \cdot n \\ &= 2^{\log_2 n} T(1) + \log_2 n \cdot c' \cdot n \\ &= nc + c' \cdot n \log n \\ &= \underbrace{nc} + c' \cdot n \log n, \quad = O(n \log n) \end{aligned}$$

Main Point

Stability of a sorting algorithm requires maintenance of nonchange in the midst of change. This is an example in the world of sorting routines of the inner dynamics of outward success, as described in SCI: The more the inner quality of awareness remains established in silence, the more outer dynamism is supported for success and fulfillment.

Connecting the Parts of Knowledge With the Wholeness of Knowledge

Merge Sort

1. Inversion-bound sorting algorithms typically examine each successive element in the input array and perform a further step to place this element in an already sorted area. The style of sorting involves a *sequential unfoldment.*
2. MergeSort proceeds by repeatedly collapsing the wholeness of the current input array into parts and then synthesizing the parts into a sorted whole. This approach yields a much faster sorting algorithm.
3. *Transcendental Consciousness* is the field of *infinite correlation*, where "an impulse anywhere is an impulse everywhere," a field of "frictionless flow".
4. *Impulses within the Transcendental field*. Established in the transcendental field, action reaches fulfillment with minimum effort. Yoga is "skill in action" – efficiency in action, "doing less, accomplishing more", whereby little needs to be done to accomplish great goals.
5. *Wholeness moving within itself.* In Unity Consciousness, the field of action effortlessly unfolds as the play of one's own Self, one's own pure consciouness.
